

# SGM811B/SGM812B Microprocessor Supervisory Circuits with Manual Reset Input

## GENERAL DESCRIPTION

The SGM811B and SGM812B are integrated microprocessor supervisory devices which can be reset under power-up, power-down or even voltage reduction brownout conditions. When  $V_{CC}$  is as low as 1V, the reset output can still operate. On the power-on state, the internal timer maintains a 200ms reset assertion, which keeps the microprocessor in the reset state until the condition is stable.

The SGM811B has an active-low nRESET output, while the SGM812B has an active-high RESET output. These devices provide three reset threshold voltage options for 3V and 3.3V voltage monitoring.

The devices also provide a manual reset (nMR) function. It can reduce damage if the device loses its control or is locked.

The SGM811B and SGM812B are available in a Green SOT-143 package. They operate over a junction temperature range of  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ .

**APPLICATION INFORMATION**

**Manual Reset Input**

The SGM811B and SGM812B provide a manual reset (nMR) function that allows users to reset the system manually. It is an active-low reset input with an internal pull-up resistor of 59kΩ. When the nMR is low, and for t<sub>RS</sub> (200ms, TYP) after nMR returns high, the reset remains active. The nMR can be driven by a CMOS logic or by a reset switch shorting to GND. If not used, leave it open or connect it to the V<sub>CC</sub>. When the device is far away from the reset switch or used in a noisy environment, a 0.1μF capacitor is recommended to connect between nMR and GND.

**Precise Reset Threshold**

When the supply voltage drops significantly for the power supply fault, the SGM811B and SGM812B can even operate normally, which greatly reduces the possibility of system failure. In addition, the internal reference voltage accuracy of the SGM811B and SGM812B is very high, which provides high reliability of the devices.

**nRESET Valid to V<sub>CC</sub> = 0V (SGM811B)**

The nRESET of SGM811B will stop sinking current and become open circuit if V<sub>CC</sub> is below 1.0V. And if a high impedance CMOS logic input is connected to the nRESET, the logic level of the CMOS input is undetermined. To solve the problem, it is recommended to use a 100kΩ resistor between nRESET and GND.

**Figure 1. nRESET Valid to V<sub>CC</sub> = 0V Circuit**

**Reset Output**

To ensure sufficient time for the power supply and microprocessor to stabilize after power-up, a 200ms (TYP) reset output will hold by the internal timer after V<sub>CC</sub> exceeds the reset threshold voltage. Similarly, a 200ms (TYP) reset output will also exist after the power supply recover from brownout or interruption that allows the power supply and microprocessor to have enough time to reach a steady state (Figure 2).

The SGM811B has an active-low nRESET output, while the SGM812B has an active-high RESET output. When V<sub>CC</sub> is as low as 1V during power-down, the nRESET of the SGM811B will continue output a low level. This not only keeps the microprocessor shutdown when the supply voltage falls, but also prevents the microprocessor occurring false actions when it powers up.

**Glitch Immunity**

The SGM811B and SGM812B have an internal filter circuit, which makes them have glitch immunity ability to bear the fast transient glitches on the power supply.

**Figure 2. Power Fail nRESET Timing**

**Interfacing to Other Devices Output**

In order to allow the SGM811B and SGM812B to be integrated with a variety of devices, it is guaranteed that the reset output is proportional to the V<sub>CC</sub> when the V<sub>CC</sub> is more than 1V. This allows the device to be used with any supply voltage between the minimum and maximum of the V<sub>CC</sub>, including 3V and 3.3V.
